# **Parallel Programming: Overview**

SESSION 3/6

## **Programming Interface for parallel computing**

OpenMP (Open Multi-Processing)

병렬 컴퓨팅을 위한 프로그래밍 인터페이스

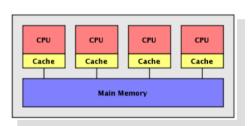

Open Specifications for Multi Processing (OpenMP) is a programming interface

for parallel computing on shared memory architecture.

### • It allows you to manage:

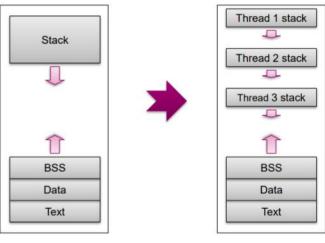

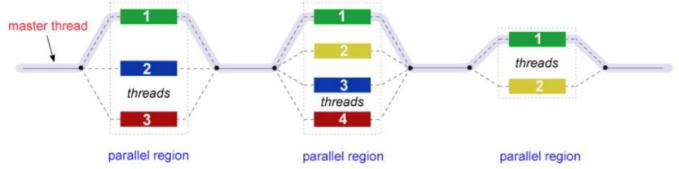

- > the creation of light processes.
- the sharing of work between these lightweight processes.
- > synchronizations (explicit or implicit) between all light processes.
- the status of the variables (private or shared).

## OpenMP is based on Fork/Join model

- 1. When program starts, one Master thread is created
- 2. Master thread executes sequential portions of the program
- 3. At the beginning of parallel region, master thread forks new threads
- 4. All the threads together now forms a "team"
- 5. At the end of the parallel region, the forked threads die!

### The OpenMP API consists of:

- compiler directives (for insertion *into sequential* Fortran/C/C++ **code**)
- a few library routines
- some environment variables

### **Advantages:**

- User-friendly
- Incremental parallelization of a serial code
- Possible to have a single source code for both serial and parallelized versions

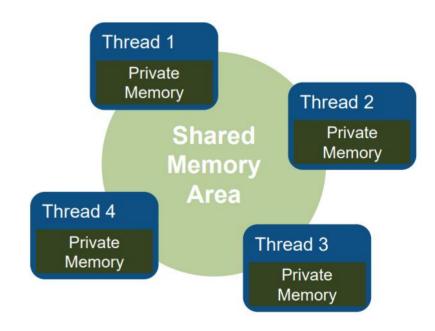

### Disadvantages:

- Relatively limited user control
- Most suitable for parallelizing loops (data parallelism)
- Performance? ~

## What is a **Shared-Memory Program**?

- One process that spawns multiple threads
- Threads can communicate via shared memory
- ➤ Read/Write to shared variables
- Synchronization can be required!
- OS decides how to schedule threads

## **OpenMP: Shared Memory**

### Shared memory model

> Threads communicate by accessing shared variables.

## • The sharing is defined syntactically

- Any variable that is seen by two or more threads is shared.
- Any variable that is seen by one thread only is private.

### • Race conditions possible

- ➤ Use synchronization to protect from conflicts.
- ➤ Change how data is stored to minimize the synchronization.

# **OpenMP: Multithreading**

## • Multithreading, natural programming model

- ➤ All processors share the same memory.
- Threads in a process see same address space.
- ➤ Many shared-memory algorithms developed.

## Multithreading is <u>hard</u>

- > Lots of expertise necessary.
- Deadlocks and race conditions.
- Non-deterministic behavior makes it hard to debug.

## **OpenMP: Process and thread**

### What is the difference?

- You need an existing process to create a thread.
- Each process has at least one thread of execution.

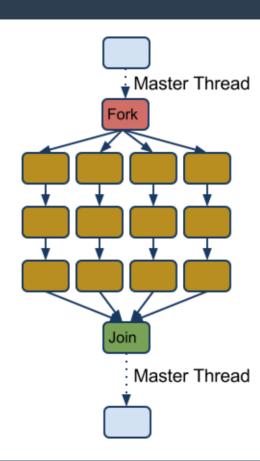

- All threads created by a process share the virtual address space of that process.
  - They read and write to the same address space in memory.
  - They share the same process and user ids, file descriptors, and signal handlers.
  - ➤ They have their own program counter value and stack pointer, and can run independently on several processors.

## **OpenMP: Terminology and behavior**

- OpenMP Team = Master + Worker
- **Parallel Region** is a block of code executed by all threads simultaneously (*has implicit barrier*)
  - $\triangleright$  The master thread always has thread id 0!
  - Parallel regions can be nested.
  - If clause can be used to guard the parallel region.

## **OpenMP: Example Code Structure**

Make "Hello World" multi-threaded...

```
int main() {
    int ID=0;
    printf("hello(%d) ", ID);;
    printf("world(%d)\n", ID);;
```

### Include OpenMP header

```
#include "omp.h"

Start parallel region with
    "default" number of threads

int main() {

    #pragma omp parallel
    {

    int ID = omp_get_thread_num();
    printf("hello(%d) ", ID);;
    printf("world(%d)\n", ID);;
}
```

## **OpenMP: Parallel Region**

A parallel region identifies a portion of code that can be executed by different threads

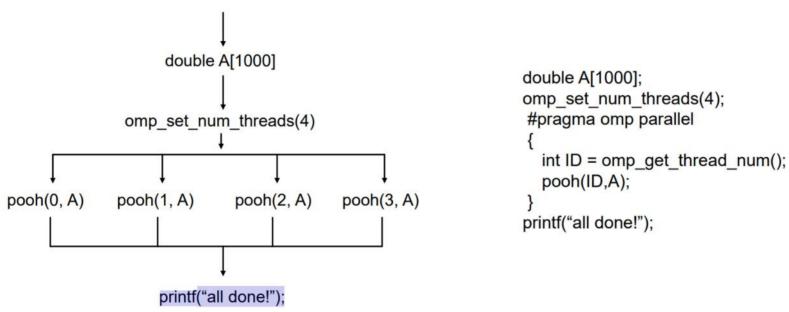

- You can create a parallel region with the "parallel" directive
- You can request a specific number of threads with **omp\_set\_num\_threads**(N)

```
\begin{array}{lll} \mbox{double A[1000];} & \mbox{double A[1000];} \\ \mbox{omp\_set\_num\_threads(4);} & \mbox{\#pragma omp parallel num\_threads(4)} \\ \mbox{\{} & \mbox{\{} & \mbox{\{} & \mbox{[ID = omp\_get\_thread\_num(); pooh(ID,A); pooh(ID,A); pooh(ID,A); } \mbox{\}} \\ \mbox{printf("all done!");} & \mbox{printf("all done!");} \end{array}
```

Each thread will call *pooh(ID,A)* function with a different value of ID

## **OpenMP: Parallel Region**

- All the threads execute the same code
- The [A] array is shared
- Implicit synchronization at the end of the parallel region

## **OpenMP: Behind the scenes...**

- The **OpenMP compiler** generates code logically analogous to that on the right.
- All known OpenMP implementations use a thread pool so full cost of threads creation
- and destruction is not incurred for each parallel region.
- Only three threads are created because the last parallel section will be invoked from the parent thread.

```
#pragma omp parallel num_threads(4)
{
   foobar();
}
```

```
void thunk() {
    foobar();
}

pthread_t tid[4];

for (int i= 1; i< 4; ++i)
    pthread_create(&tid[i],0,thunk, 0);

thunk();

for (int i = 1; i< 4; ++i)
    pthread_join(tid[i]);</pre>
```

# **OpenMP: Constructs Parallel Region**

### Parallel region

- Thread creates team, and becomes master (id 0).
- All threads run code after.
- Barrier at end of parallel section.

- shared
- private
- firstprivate
- default
- threadprivate
- lastprivate
- reduction

## **OpenMP: Data Sharing Attributes**

#### Shared

The variable inside the construct is the same as the one outside the construct.

- In a parallel construct this means all threads see the same variable but not necessarily the same value.
- Usually need some kind of synchronization to update them correctly.

```
int x=1;
#pragma omp parallel private(x) num_threads(2)
{
     X++;
     printf("%d\n",x);
}
printf("%d\n",x);
Prints 1
```

### **Private**

The variable inside the construct is a **new** variable of the same type with an **undefined** value

- In a parallel construct this means all threads have a different variable
- Can be accessed without any kind of synchronization

# **OpenMP: Data Sharing Attributes**

```
int x=1;
#pragma omp parallel firstprivate(x) num_threads(2)
{
    x++;
    printf("%d\n",x);
}
printf("%d\n",x);
Prints 1
```

### **F**irstprivate

The variable inside the construct is a **new** variable of the same type but it is initialized to the original value of the variable

- In a parallel construct this means all threads have a different variable with the same initial value
- Can be accessed without any kind of synchronization

#### And default. What is the default?

- If there is a **default clause**, what the clause says
  - **none** means that the compiler will issue an error if the attribute is not explicitly set by the programmer.
- Otherwise, depends on the construct
  - For the parallel region the default is shared.

# **OpenMP: Synchronization**

## Directives to synchronize thread team or control thread access to code fragments

<b>\$OMP MASTER</b>	Execute section only with master thread (no implied barrier).	
<b>\$OMP CRITICAL</b>	Restrict access to one thread at a time (otherwise block).	
<b>\$OMP BARRIER</b>	Synchronize all threads.	
<b>\$OMP ATOMIC</b>	Special case of CRITICAL, the statement following allows a specific memory location to be updated atomically (no multiple writes, can take advantage of specific hardware instructions for atomic writes).	
<b>\$OMP FLUSH</b> [(list)]	Ensure threads have consistent view of shared variables (else just the named list).	
\$OMP ORDERED	Execute code in same order as under sequential execution.	
\$OMP SINGLE	Block executed by only one thread (implied BARRIER and FLUSH at the end)	

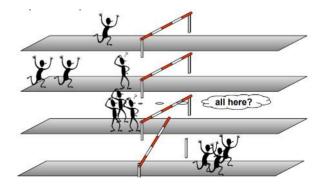

# **OpenMP: Barrier**

When a thread reaches a barrier, it only continues after all the threads in the same thread team have reached it.

- Each barrier must be encountered by all threads in a team, or none at all
- The sequence of work-sharing regions and barrier regions encountered must be same for all threads in team
- Implicit barrier at the end of: do, parallel, single, workshare

# **OpenMP: Caution Race Condition**

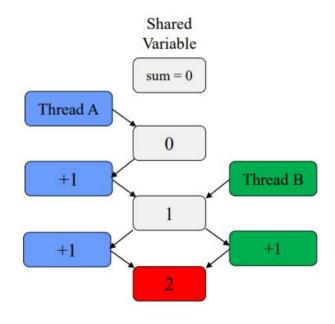

When multiple threads simultaneously read/write

Multiple OMP solutions:

- **Reduction**
- > Atomic
- > Critical

```
#pragma omp parallel for private(i) shared(sum)
for (i=0; i<N; i++) {
   sum += i;
}</pre>
```

Should be 3!

# **OpenMP: Critical Section**

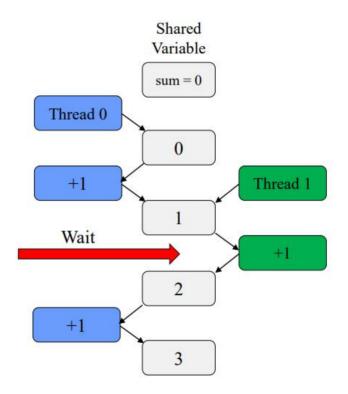

One solution: use critical

Only one tread at a time can execute a critical section

```
#pragma omp critical
{
    sum += i;
}
```

Downside ?
YES SLOOOOWWW
Overhead and serialization

## **OpenMP: Atomic**

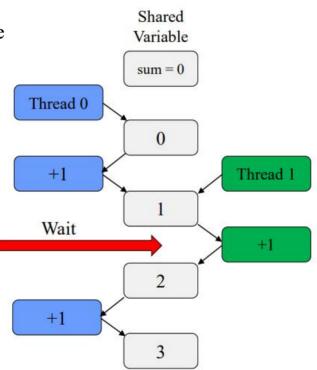

**Atomic** provides mutual exclusion but only applies to the update of a memory location.

**Atomics** like "mini" critical
Only one line
Certain limitations

#pragma omp atomic
sum += i;

Hardware controlled
Less overhead the critical

## **OpenMP: Reduction**

### #pragma omp reduction (operator:variable)

- Avoids race condition
- Reduce variable must be shared
- Makes variable private, then performs operator at end of loop
- Operator cannot be overloaded (c++)

One of: +,\*,-,/ (and &,^,|,&&,||)

OpenMP 3.1: added min and max for c/c++

```
#include <omp.h>
#include <stdio.h>
int main() {
   int i;
   const int N = 1000;
   int sum = 0;

#pragma omp parallel for private(i) reduction(+: sum)
   for (i=0; i<N; i++) {
      sum += i;
   }

   printf("reduction sum=%d (expected %d)\n", sum, ((N-1)*N)/2);</pre>
```

## **OpenMP: Scheduling**

#pragma omp parallel for schedule(type [,size])

### **Scheduling types:**

### Static

- Chunks of specified size assigned round-robin

### **Dynamic**

- Chunks of specified size are assigned when thread finishes previous chunk

#### Guided

- Like dynamic, but chunks are exponentially decreasing
- Chunk will not be smaller than specified size

### **Runtime**

- Type and chunk determined at runtime via environment variables

## **OpenMP: Scheduling**

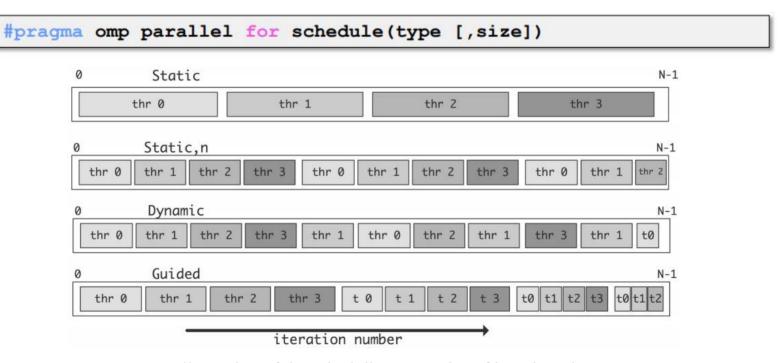

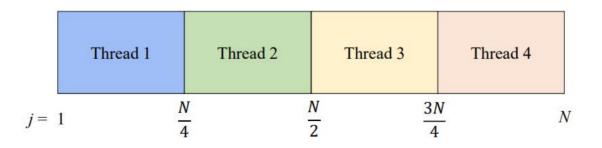

Illustration of the scheduling strategies of loop iterations.

# **OpenMP: Scheduling**

How does a loop get split up? In MPI, we have to do it manually!!!

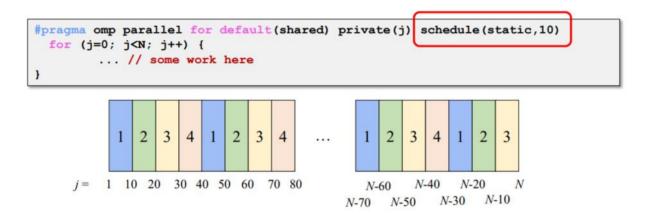

If you do not tell what to do, the compiler decides Usually compiler chooses "static" - chunks of N/p

# **OpenMP: Static Scheduling**

### You can tell the compiler what size chunks to take?

Keeps assigning chunks until done.

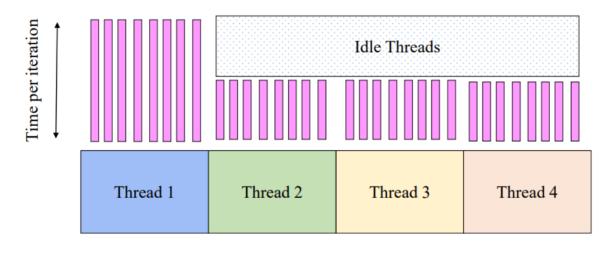

Chunk size that is not a multiple of the loop will results in thread with uneven numbers.

# **OpenMP: Problem with Static Scheduling**

What happens if loop iterations do not take the same amount of time?

## Load imbalance

# **OpenMP: Dynamic Scheduling**

Chunks are assigned on the fly, as threads become available.

When a thread finishes on chunk, it is assigned another

Caveat: higher overhead than static!

# **OpenMP Examples**

## **OpenMP: API**

- API for library calls that perform useful functions
- Must include "omp.h"
- Will not compile without OpenMP compiler support

```
#include <omp.h> //<-- necessary header file for OpenMP API
#include <stdio.h>
int main(int argc, char *argv[]) {
    printf("OpenMP running with %d threads\n", omp_get_max_threads());

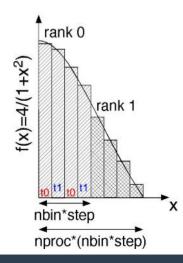

#pragma omp parallel
    {
        //Code here will be executed by all threads
        printf("Hello World from thread %d\n", omp_get_thread_num());
    }
    return 0;
}
```

## **OpenMP: Compute Pl**

```
#include <omp.h>
                                                              Promote scalar to an
static long num_steps = 100000;
                                        double step:
                                                             array dimensioned by
#define NUM_THREADS 2
                                                              number of threads to
                                                             avoid race condition.
void main ()
          int i, nthreads; double pi, sum[NUM_THREADS];
          step = 1.0/(double) num_steps;
          omp_set_num_threads(NUM_THREADS);
  #pragma omp parallel
                                                      Only one thread should copy
         int i, id, nthrds;
                                                      the number of threads to the
         double x:
                                                      global value to make sure
         id = omp_get_thread_num();
                                                      multiple threads writing to the
         nthrds = omp_get_num_threads();
                                                      same address don't conflict.
         if (id == 0) nthreads = nthrds;
          for (i=id, sum[id]=0.0;i< num_steps; i=i+nthrds) {
                                                               This is a common
                  x = (i+0.5)*step;
                                                               trick in SPMD
                  sum[id] += 4.0/(1.0+x*x);
                                                               programs to create
                                                               a cyclic distribution
                                                               of loop iterations
          for(i=0, pi=0.0;i<nthreads;i++)pi += sum[i] * step;
```

GOAL: The following code computes the  $\pi$  number by using a numerical evaluation of an integral by a rectangle method.

$$\pi = \int_0^1 \frac{4}{1+x^2} dx \cong \Delta \sum_{i=0}^{N-1} \frac{4}{1+x_i^2}$$

## **OpenMP: Compute PI with padding**

```
#include <omp.h>
static long num steps = 100000;
                                     double step:
#define PAD 8
                          // assume 64 byte L1 cache line size
#define NUM THREADS 2
void main ()
         int i, nthreads; double pi, sum[NUM_THREADS][PAD];
         step = 1.0/(double) num_steps;
         omp_set_num_threads(NUM_THREADS);
  #pragma omp parallel
                                                            Pad the array
                                                            so each sum
        int i, id,nthrds;
                                                            value is in a
        double x;
                                                            different
        id = omp_get_thread_num();
                                                            cache line
        nthrds = omp_get_num_threads();
        if (id == 0) nthreads = nthrds;
         for (i=id, sum[id]=0.0;i< num_steps; i=i+nthrds) {
                 x = (i+0.5)*step;
                 sum[id][0] += 4.0/(1.0+x*x);
         for(i=0, pi=0.0; i<nthreads; i++)pi += sum[i][0] * step;
```

Remark about false sharing: If independent data elements happen to sit on the same cache line, each update will cause the cache lines to "slosh back and forth" between threads.

HotFix with PAD, elements you use are on distinct cache lines.

threads	1 <sup>st</sup> SPMD	1st SPMD padded
1	1.86	1.86
2	1.03	1.01
3	1.08	0.69
4	0.97	0.53

Results

Padding arrays requires deep knowledge of the cache architecture, also be careful...

## OpenMP: Compute PI with omp for reduction

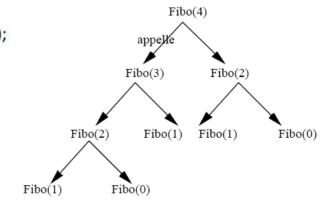

```
#include <omp.h>
static long num steps = 100000;
                                              double step;
void main ()
   int i:
                 double x, pi, sum = 0.0;
                                               Create a team of threads ...
                                               without a parallel construct, you'll
    step = 1.0/(double) num steps;
                                               never have more than one thread
    #pragma omp parallel
                                      Create a scalar local to each thread to hold
        double x;
                                      value of x at the center of each interval
       #pragma omp for reduction(+:sum)
           for (i=0;i< num steps; i++){
                                                     Break up loop iterations
                 x = (i+0.5)*step;
                                                      and assign them to
                                                     threads ... setting up a
                 sum = sum + 4.0/(1.0+x*x);
                                                      reduction into sum.
                                                     Note ... the loop indix is
                                                     local to a thread by default.
         pi = step * sum;
```

## **OpenMP: Fibonacci**

```
fib(0) = 1
fib(1) = 1
fib(n) = fib(n-1) + fib(n-2)
avec n \in \mathbb{N}
```

## **OpenMP: Quicksort**

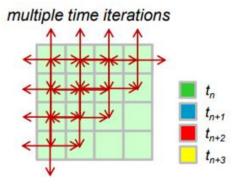

```
void quick_sort (int p, int r, float *data)
                                         void par_quick_sort (int n, float *data)
  if (p < r) {
     int q = partition (p, r, data);
                                            #pragma omp parallel
     #pragma omp task
                                              #pragma omp single nowait
     quick_sort (p, q-1, data, low_limit);
                                              quick sort (0, n, data);
     #pragma omp task
                                                                                9 -3 5 2 6 8
     quick_sort (q+1, r, data, low_limit);}
                                                                                                5 9 6
```

## **OpenMP: Gauss-Seidel**

```
void gauss seidel(int tsteps, int size, int TS, int (*p)[size]) {
  int NB = size / TS:
  #pragma omp parallel
  #pragma omp single
  for (int t = 0; t < tsteps; ++t)
    for (int ii=1; ii < size-1; ii+=TS)</pre>
      for (int jj=1; jj < size-1; jj+=TS) {</pre>
        #pragma omp task depend(inout: p[ii:TS][ij:TS])
            depend(in: p[ii-TS:TS][jj:TS], p[ii+TS:TS][jj:TS],
                         p[ii:TS][jj-TS:TS], p[ii:TS][jj:TS])
          for (int i=ii; i<(1+ii)*TS; ++i)</pre>
            for (int j=jj; j<(1+jj)*TS; ++j)</pre>
                p[i][j] = 0.25 * (p[i][j-1] * p[i][j+1] *
                                   p[i-1][i] * p[i+1][i];
```

**Gauss-Seidel Method** is used to solve the linear system Equations. It is a method of iteration for solving n linear equation Ax=b with the unknown variables.

## **OpenMP: Performance Tips...**

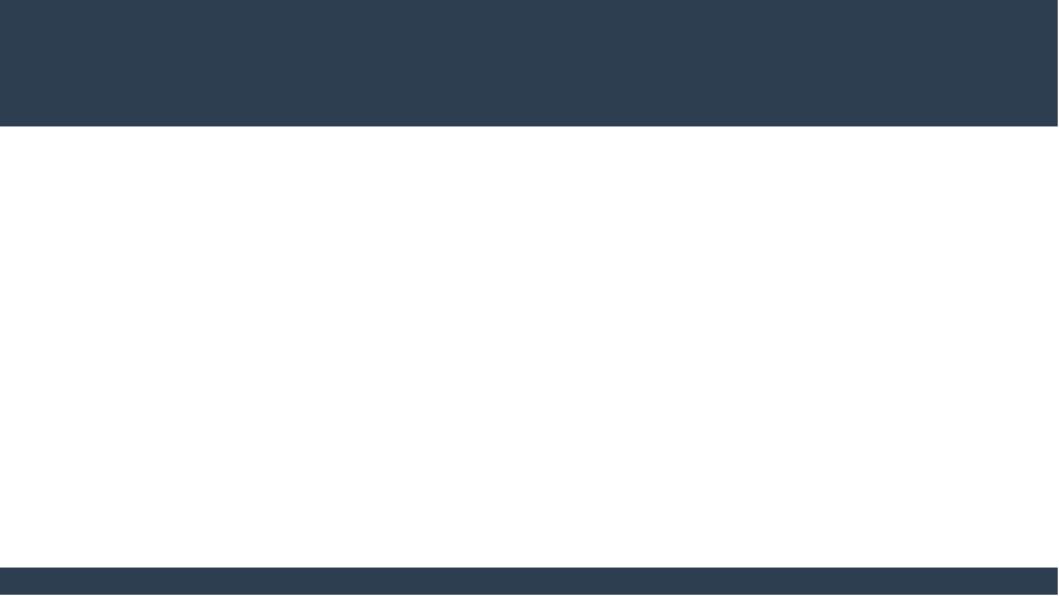

- Avoid serialization!
- Avoid using **#pragma omp parallel** for before loop.
- Use **reduction** whenever possible.
- Minimize I/O
- Minimize critical
  - Use **atomic** instead of **critical** where possible.

Thank you for your attention!

## **OpenMP: Cholesky Factorization**

The Cholesky factorization, also known as Cholesky decomposition, is a process of breaking down of a Hermitian, positive-definite matrix into the product of a lower triangular matrix and its conjugate transpose, which is important for quick numerical solutions in linear algebra.

```
1: Input: Dictionary \mathbf{D}, signal \underline{x}, target sparsity K or target error \epsilon
2: Output: Sparse representation \underline{\gamma} such that \underline{x} \approx \mathbf{D}\underline{\gamma}
3: Init: Set I := (), \mathbf{L} := [1], \underline{r} := \underline{x}, \underline{\gamma} := \underline{0}, \underline{\alpha} := \mathbf{D}^T\underline{x}, n := 1
4: while (stopping criterion not met) do
5: \hat{k} := \operatorname{Argmax} |\underline{d}_{k}^{T}\underline{r}|
6: if n > 1 then
7: \underline{w} := \operatorname{Solve} for \underline{w} \in \mathbf{L}\underline{w} = \mathbf{D}_{I}^{T}\underline{d}_{k}^{*} }
8: \mathbf{L} := \begin{bmatrix} \mathbf{L} & \underline{0} \\ \underline{w}^{T} & \sqrt{1 - \underline{w}^{T}\underline{w}} \end{bmatrix}
9: end if
10: I := (I, \hat{k})
11: \underline{\gamma}_{I} := \operatorname{Solve} for \underline{c} \in \mathbf{L}^{T}\underline{c} = \underline{\alpha}_{I}^{*} }
12: \underline{r} := \underline{x} - \mathbf{D}_{I}\underline{\gamma}_{I}^{*}
13: n := n + 1
```

```
void cholesky (int ts, int nt, double* a[nt][nt]) {
  for (int k = 0; k < nt; k++) {
